Redkozemel'nye elementy: poluchenie, analiz, primeneniye (Rare Earth Elements; Extraction, Analysis and Application) Moscow, Izd-vo AN SSSR, 1958. 351 p. 2,300 copies printed.

Resp. Ed.: D. I. Ryabchikov, Professor; Editorial Board: I. P. Alimarin, Corresponding Member, USSR Academy of Sciences, I. I. Kormerskiy, Doctor of Chemical Sciences; A. V. Karyakin, Candidate of Technical Sciences; V. I. Kuznetsov, Doctor of Chemical Sciences, N. M. Senyavin, Candidate of Chemical Sciences, and Yu. S. Sklyarenko, Candidate of Chemical Sciences; Eds. of Publishing House: D. M. Fridman and T. G. Levi; Tech. Ed.: M. G. Markovich.

PURPOSE: This book is intended for scientists, chemists, teachers and students of higher educational institutions, chemical and industrial engineers, and other persons concerned with the extraction, preparation, analysis, or study of rare earth elements.

COVERAGE: This collection contains reports presented at the June 1956 Conference on Rare Earth Elements at the Institute of Geochemistry and Analytical Chemistry imeni V. I. Vernadskiy of the Academy of Sciences USSR. The articles treat chemical methods of separating rare earth mixtures, methods of processing rare earth ores, ion exchange chromatography, chemical analysis, and some industrial applications of rare earths. Aside from contributing authors, the editors mention the following Soviet scientists, who are studying rare earth elements, rare earth deposits, extraction methods, and the preparation of oxides and salts: Martynov, Mel'nikov, Chrushchov, Bolikov, Miarkevskiy, Chereps, Dunkov, Belousov, Dunkov and especially, N. A. Orlov, who first obtained the majority of rare earth elements in the pure state, separated many complex molecular compounds of these elements, and determined their specific properties. References are given at the end of each article.

TITLE: The Theory of the Separation of Rare Earths by Means of Chromatographical Methods (Teoriya razdeleniya redkozemel'nykh elementov khromatograficheskim metodom).

PERIODICAL: Zhurnal Neorganicheskoy Khimii, 1958, Vol. 3, Nr 1, pp. 66-73 (USSR).

ABSTRACT: Results of the application of statistical methods with respect to the theory referred to in the title are described in the present report, and theoretical results are compared with the experimental ones. Washing out of chromatographic apexes of curves. The efficiency of separation of the ions of two elements depends 1st on the static factors of separation (ratio of the coefficients of sorption of the ions) and secondly on kinetic factors. The coefficients of diffusion D_c (in the grains of the adsorbent) and D_p (in the solution) are described by means of equations (1). These coefficients of autodiffusion were measured in several elaborate investigations. The velocity of diffusion of the rare earths in sulfopolystyrene-resin KU-2 was measured by the authors. D_c is equal to 10^{-1} cm^2/sec. If Dc is known, the part of the

Card 1/5

The Theory of the Separation of Rare Earths by Means
of Chromatographical Methods.

wing solution and is approximately proportional to $\frac{v}{r}$. Other kinetic
factors can also be seized with the same method. The equation (3) can
be directly applied in the cases where the distribution of ions is con=
sidered in the length of the column. Experimental investigation of the
apexes. For experimentally re-examining the equation:

$$\frac{(\Delta V^2)}{V} = a_1 + b_1 v \int^{\neg 1} \quad (7)$$

which was derived by applying
(3'), the washing-out of the

apexes of Rb^{86}, which was achieved by rinsing of the column with "Espa=
tite-1"-resin by 0,1 n HCl (reference 1) was investigated. The tests
confirmed the theoretically required dependence of the width of the band
on the length of the column and proved the correctness of the equation
(7). The results of one of the tests are shown in table 1 and figure 1.
A diagram was drawn of the results of each test (figures 1, 2). Investi=
gation of the kinetics of the ion-exchange of rare earths. The above in=
vestigation does not yet permit to draw any definite conclusions on the
role of individual kinetic factors with the separation, and on the in=
fluence of the complex-former. As is generally known, the apexes of rare
earths are largely expanded with the decreasing pH of the solutions of

Card 3/5

The Theory of the Separation of Rare Earths by Means
of Chromatographical Methods.

78-1-13/43

citric acid. The kinetics of desorption of several elements in $5^o/o$ so=
lution of this acid with different pH (adjusted with ammonia) were inve=
stigated for clarifying these problems (reference 5). The values of the
coefficients of diffusion of the ions of rare earths within the resin-
grains (D_c) were computed from the curves of desorption. The found con=
stancy of the D_c-values confirms the mechanism of diffusion of the de=
sorption. It is shown in table 3 that the average values of these coef=
ficients are independent on the composition of the solution. It hence
results that the complex-former has no specific effect with low pH. It
results from table 4 in which the dependence of the coefficients of dif=
fusion on the pH for La^{140} and Eu^{154} are reproduced that D_c increases
to some extent with increasing pH. The washing out of the apexes is
mainly explained by processes in the solution. Table 5 shows the influ=
ence of the atomic number on the value of the coefficient of diffusion.
The heavy rare earths diffuse many times more rapidly in resin than do
the light. The conditions of separation. An increase of the coefficient
of sorption prolongs the duration of separation and viceversa.
There are 3 figures, 5 tables, and 7 references, 5 of which are Slavic.

TITLE: The Separation of Carbon Isotopes by the Thermodiffusion of
Carbon Monoxide (Razdeleniye izotopov ugleroda termodiffuziyey
okisi ugleroda)

PERIODICAL: Zhurnal Tekhnicheskoy Fiziki, 1958, Vol. 28, Nr 4, pp. 881-
-885 (USSR)

ABSTRACT: The investigations described here had already been terminated
in 1953, when reference 9 was published. - The separation of
carbon isotopes by means of the thermal diffusion of carbon
monoxide in glass towers with a diameter of 9 and 14,5 mm, a
length of 1 and 2 m with a platinum wire of 0,4 - 0,6 mm dia-
meter as a heating-element were investigated here. The
experimental results are in agreement with the theory by
Dzhons (Jones ?) - Ferri - Onsager. - It is shown that in a
number of cases the use of carbon monoxide as working gas
has certain advantages as compared to the use of methane. The
ratio of the separating factor of carbon to that of oxygen
differs from the theoretical value. The latter is equal to   2.
The magnitude of the deviation depends on the steam-content

             Barabanov, S.R., Tunitskiy, N.N.

TITLE: The Effect of the Capacity of **Sulphostyrene** ...... on the
             Ion-Exchange Equilibrium (O vliyanii yemkosti sul'fostirol'nykh
             kationov na ionoobmennoye ravnovesiye)

PERIODICAL: Zhurnal fizicheskoy khimii, 1958, Vol. 52, Nr 6, pp.
             1423-1424 (USSR)

ABSTRACT: The problem of the influence of the capacity of the ionites
             on their selectivity is insufficiently investigated as, e. g.
             the assumption of the paper by B.uman (Ref 1) .... of Arilies,
             and in the experiments conducted by Boyd (Ref 3) besides
             the structural change also a chemical change of the
             composition of the cationites may have taken place. In order
             to avoid the disadvantages of the **desulphurization** method in
             the investigation of the selectivity the authors synthetized
             highly acidous **sulphostyrene** cationites of a different content
             of sulfo groups and interchain-bonds according to the method
             of direct **sulphurization**. The equilibria Na-H, R'-H-and
             Ca-H were investigated with 0,1 n solutions and samples
             having been used; the selectivity of the exchange was

Card 1/2

The Effect of the Capacity of **Sulphostyrene** Cations on SOV/76-32-6-40/46
the Ion-Exchange Equilibrium

determined according to an equation. From the mentioned
data of the experiments may be seen that the assumption
can be made that the selectivity of Rb and Na in resins
of small capacity is smaller than in those of high capacity.
The experiments carried out with the equilibrium Ca-H also
showed that with the increase of the capacity of the resin
also the selectivity increases. The individual values as
well as the corresponding resin compositions are given.

TITLE: On the Mass Spectra of Large Molecules (O mass-spektrakh bol'shikh molekul)

ABSTRACT: For the purpose of investigating the dissociation processes in the case of an electron impact, mass spectra of n-nonane marked at a definite point with C^{13} (n-nonane-5C^{13}) were taken. By comparing them with the mass spectra of normal n-nonane the proportion of ions containing C^{13} was determined. The results can only be explained by assuming that the fragment ions form by a breaking of the binding between 2 carbon atoms. The molecule is broken in most cases into 3 fragments with C-atoms. The ions forming are strongly stimulated. Test results show that the stimulation energy of the initial ion, up to the moment of dissociation, can only spread to part of its degrees of freedom whereas H. Eyring (Ref 3) assumed a statistical distribution of

TITLE: On the Mass Spectra of Large Molecules (O mass-spektrakh
krupnykh molekul)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol 123, Nr 1, pp 120-122
(USSR)

ABSTRACT: It is known that the bombarding of polyatomic molecules by
electrons (energy 50-100 eV) leads to the ionization and
dissociation of these molecules. In order to make it possible
to draw unique conclusions concerning the mechanism of
dissociation, the authors investigated the mass spectrum of
n-nonane-5C^{13}. Carbon monoxide containing 51% C^{13} was used for
the synthesis. The scheme for the synthesis is given.

The nonane and n-nonane-5C^{13} mass spectra, which were corrected
to their natural content of C^{13} and were determined under the
usual conditions by means of the device MI-1303, are given in
a table. A second table shows the percentages of the ions

Card 1/3   containing C^{13}. If the molecule of n-nonane-5 C^{13} were

dissociated by a simple stripping of bonds, the ions of the type $C_2H_5^+$, $C_3H_7^+$, $C_4H_9^+$ would contain no carbon C^{13}.
The fragment-like ions of other types are essentially formed by the stripping of hydrogen atoms from the original ions.
In general, the dissociation of large molecules in an electron collision develops as follows: First, "head ions" ("golovnyye" iony) are produced with equal probability from all parts of the molecule (by the capture of a hydrogen atom) with an even number of ions. Next, some of these ions decay, accompanied by the stripping of hydrogen ions, and they form a complete mass spectrum of the substance. These facts correspond to the conclusions drawn from the investigations of the mass spectra from large molecules. At present the following is assumed: The excitation energy is distributed over the entire molecule after the electron collision and this molecule then dissociates according to the decay law. The authors from this point of view investigated 2 molecules of normal structure, as e.g. n-hexane C_6H_{14} and n-tetratetracontane $C_{44}H_{90}$. Contrary to expectations, the experiments showed the following: The larger the molecule (in the case of equal structure) the smaller will be

Card 2/3

On the Mass Spectra of Large Molecules

the content of molecular ions in its mass spectrum. Thus, the existence of even the mass spectra of large molecules must be explained by the fact that the energy transmitted by the electron cannot propagate over the entire molecule (before its dissociation). This supposition agrees with data concerning the investigation of initial ranges of ionization curves (Ref 7), and it makes it possible to explain the results obtained by the authors: If the electron incides with equal probability upon any part of the molecule, and if the energy transmitted by it is propagated before dissociation only within a small part of the molecule, it is just this part of the molecule that is "knocked out" in form of a fragment-ion. The ions produced in this way contain the main portion of the excitation energy and therefore dissociate easily accompanied with the stripping of hydrogen atoms. There are 2 tables and 7 references, 1 of which is Soviet.

TITLE: The Separation of the Isotopes of Carbon and Oxygen by the Recti-
               fication of CO in a 12-m Column (Razdeleniye izotopov ugleroda i
               kisloroda rektifikatsiyey CO na 12-metrovoy kolonne)

PERIODICAL: Zhurnal prikladnoy khimii, 1959, Vol XXXII, Nr 3, pp 531-536
               (USSR)

ABSTRACT: The stable carbon isotope C^{13} is used for studying the dis-
               sociation of molecules, for resolving optical and radio-fre-
               quency spectra, etc. The stable oxygen isotope O^{18} is also
               needed for many chemical investigations. An apparatus has been
               developed containing a packed rectification column (Figure 1)
               for the low-temperature rectification of CO. The upper re-
               servoir of the column contained 400 - 600 cm³ CO with a lowered
               C^{13} content. This reservoir was filled at regular intervals
               with CO of normal C^{13} content. After 52 days the coefficient
               of separation of carbon reached 67.8, that of oxygen 23.6. On
               reaching this coefficient the column produced within 36 days
               82 g of CO with a content of C^{13} from 30 - 37% and O^{18} from
               3.5 - 4.2%. This corresponds to 34.5 times and 21 times of the

TITLE: Investigation of the Kinetics of Ion Exchange Sorption
             (Issledovaniye kinetiki ionoobmennoy sorbtsii).II. Kinetics
             of Exchange With Participation of Hydrogen Ions (II. Kinetika
             obmena s uchastiyem vodorodnykh ionov)

ABSTRACT: The investigation under review deals with the process of the
             complete cation exchange and limiting cases of the exchange -
             the self-diffusion and diffusion of ions of microcomponents
             in the resin - of various cation forms. In the case of a com-
             plete exchange the investigation concerned the initial as
             well as the end stage at which one of the exchanging cations
             was present in a small quantity. The effective diffusion co-
             efficients (DC), that were computed for this case, were com-
             pared with the (DC) for the ions of the microcomponents. To
             simplify calculations the authors investigated along with
             the full exchange in the resin, the exchange of the cations
             in cation exchanger membranes (from sulphurized polystyrene

Card 1/4

Investigation of the Kinetics of Ion Exchange Sorption. II. Kinetics
of Exchange With Participation of Hydrogen Ions

resin). In fact, when exchanging cations of different mobili-
ties through the membrane, an electric field is generated
(as in the case of the complete exchange in resin), which
can be measured. The kinetics of the cation exchange was in-
vestigated on polystyrene resins with various contents (high,
normal, low) of divinyl benzene. The kinetic experiments
took place at 19-20$°$. Under investigation were monovalent
cations in 0.165 n and bivalent cations in 0.25 n and 1 n
solutions. An adsorption or desorption method was applied,

with use of the isotopes Na^{24}, Rb^{96}, Sr^{89} and Ca^{45}. The
above mentioned membranes contained 70% of resin KU-2 and
30% divinylbenzene. It was observed (Fig 1) that the quickest

exchange is that of H^+-ions from the resin with Na^+-ions
of the solution, and the slowest is the diffusion of the
ions of the microcomponents of sodium in the resin (in the
H-form). Values are given of the effective (DC) for the

Card 2/4   exchange between the Na^+ and H^+ in the resin (with lower

SOV/76-33-4-28/32

Investigation of the Kinetics of Ion Exchange Sorption. II. Kinetics of Exchange With Participation of Hydrogen Ions

divinylbenzene content) (Table 1), as well as the (DC) of Na^+ being found in microamounts in the resin (Table 2), and it proceeds therefrom that the complete exchange between Na^+ and H^+ takes place with a higher effective (DC) than are the (DC) of the ions of the microcomponents of sodium, which diffuse in resin (in the H-form). The same also holds for rubidium. The effective (DC) increase with a decrease in the relative content of H-ions in the resin which is explained by an anomalously greater mobility of the H-ions in the resin. The ions Na^+, Ca^{2+} and Ce^{3+} were investigated on the cation exchanger membrane. It was observed that (Fig 4) the effective (DC) increase with the decrease of the relative content of H-ions in the solution. There are 6 figures, 2 tables, and 7 references, 1 of which is Soviet.

5(4)
AUTHORS: Fedoseyeva, O. P., Tunitskiy, N. N. (Moscow)

ABSTRACT: The process mentioned in the title was investigated on the
cation exchanger KU-2. The limiting cases of self-diffusion
and the diffusion of the ion microcomponents with various
cation occupation of the exchanger were measured together
with the total exchange. Figure 1 shows the dependence of
the diffusion coefficient for strontium on the composition
of the resin containing Sr and H ions (upper curve) and Sr and
Na ions (lower curve). The diffusion coefficients of the Sr
ions show a linear dependence on the composition of the solution.
The diffusion proceeds faster in resin containing H and Na
ions than in resin containing Sr ions only. Table 1 shows the
results of the experimental series carried out in order to

Card 1/3

Investigation of the Kinetics of Ion Exchange Sorption.   SOV/76-33-5-28/33
3. Complete Exchange Between Univalent and Bivalent Ions in Resins

determine the diffusion coefficients of the ion microcompo-
nents and the coefficients of self-diffusion. Hence it
appears that univalent and bivalent ions diffuse faster in a
resin containing univalent ions than in a resin containing
bivalent ions. This dependence can be explained to some degree
by the different swelling capability of the resin containing
univalent and bivalent ions (Table 2). The swelling capa-
bility depends more on the cation occupation of the resin
than on the concentration of the swelling solution. Figures
2-4 show the results of the investigation of the exchange
between univalent ions (Na^+ and H^+) and bivalent ions
(Ca^{2+} and Sr^{2+}) as well as the curves of the total exchange,
the self-diffusion and the diffusion of the ion microcompo-
nents. In all cases, the self-diffusion of the sodium ions
was the fastest, that of the strontium ions the slowest
process. Figures 5 and 6 compare the kinetics of the ex-
change of Sr ions from the resin for H ions from the solution
with the exchange for Na ions from the solution. There are
6 figures, 2 tables, and 4 references, 2 of which are Soviet.

TITLE: The Ionization and Dissociation of the Molecules of n-Octane and
             n-Nonane by Monoenergetic Electrons (Ionizatsiya i dissotsiatsiya
             molekul n-oktana i n-nonana monoenergeticheskimi elektronami)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 3, pp 612-615 (USSR)

ABSTRACT: In the introduction to the present paper investigations carried
             out by V. L. Tal'roze and Ya. L. Frankevich on the determination
             of the affinity of some molecules are mentioned (Ref 4). In the
             present paper the formation of fragment ions and the excitation
             of molecule ions by monoenergetic electrons is investigated. This
             is done by investigating the occurrence of fragment- and molecule ions

             of n-octane, n-octane-2D$_1$ and n-nonane-5D^{13}. Measurements were

             carried out in a special mass spectrograph, and for obtaining the
             monoenergetic electrons a method developed by R. E. Fox (Ref 6)
             was used. Tables 1 and 2 show the potentials of molecule- and

             fragment-ions of the type $C_nH_{2n+1}^+$ and $C_nH_{2n}^+$ occurring in this mass

             spectrograph, and two diagrams show the ion flux of molecule- and
             fragment ions in dependence on electronic energy. From these

TITLE: Dissociation of Large Molecules in Electron Impact

PERIODICAL: Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1960, Vol. 24, No. 8, pp. 975-978

TEXT: The present paper generally deals with the interaction between an electron and a large molecule. Usually, it is assumed in such a case that the molecular ion takes part in the dissociation as a whole. The calculations of the authors (Ref. 6) showed, however, that also with usual electron energies ($\sim$70 ev) the large molecules (C_{44}) may dissociate not in the same way as is the case in the experiments. A hypothesis is suggested to explain this fact. It says that in the processes accompanied by a dissociation of the molecule only a limited number of vibrational degrees of freedom is excited and that dissociation takes place in the region of excitation. It is demonstrated that this hypothesis can be accurately controlled. It is pointed out

Card 1/3

Dissociation of Large Molecules in Electron
Impact

82833
S/048/60/024/008/010/017
B012/B067

that if the electron "arrives" with approximately equal probability in
any part of the molecule and if the excitation energy transmitted by this
electron is distributed only over a small part of the molecule - in the
dissociation exactly this part of the molecule would be bound to "fall
out" in the form of a fragment ion. Hence, the fragment ions would be
bound to form with equal probability from any part of the molecule. The
experiments conducted by the authors confirmed that the main fragment ions
are actually formed in this way. It is pointed out that this is the case
in the entire range from 1000 ev to energies which are by $1 \div 2$ ev above
the potential at which the corresponding ion is formed. The investi-
gations of the mass spectra in the case of such high electron energies
were conducted by Yu. M. Miller. The experiments made by the authors
showed that the mass spectra of the molecules investigated are equal
not only at $50 \div 70$ ev but also at any electron energy. This proves
that the interaction between electron and molecule is independent of
the dimensions of the molecule which confirms the hypothesis on the
"local" character of this interaction. In conclusion, considerations are
made for the case of double bonds and other possible couplings of bonds

TITLE: Dissociation of large molecules under electron impact

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 24, 1961, 14, abstract 24B79 (Tr. Tashkentsk. konferentsii po mirn. ispol'zovaniyu atomn. energii, v. 1, 1959. Tashkent, AN UzSSR, 1961, 378 – 382)

TEXT: Comparison has been made the mass spectra of synthesized n-octane and n-octane-$2d_1$, n-nonane and n-nonane-$5C^{13}$ from normal and labeled molecules. The probability of the formation of "leading" fragment ions of the C_nH_{2n+1} type was found to be roughly the same for any part of a molecule, i. e. by breaking two C – C bonds. The intensities of the remaining ions were calculated on the assumption that they are formed from parts of the molecules whose compositions correspond to the leading ions. The results of the calculation are in very good agreement with experimental data. In

TITLE: Change in the selectivity of monofunctional sulfonated cation exchangers as a function of the concentration of the initial electrolyte solutions and the charges of exchanging ions

PERIODICAL: Zhurnal fizicheskoy khimii, v. 35, No. 1, 1961, 189-191

TEXT: The authors wanted to study the selectivity of the sulfonated cation exchanger of the type KY-2 (KU-2). The exchanger was obtained by copolymerization of styrene with divinyl benzene and the subsequent sulfonation by means of chloro sulfonic acid. In H form, this resin is a polyelectrolyte, whose anions are strongly bound to the resin, and whose cations are mobile. The following aspects were investigated through a study of the equilibrium of ion exchange: a) the dependance of selectivity on the exchanger capacity change; b) the dependance of selectivity on the cross linking; c) on the initial

Card 1/3

concentration of the electrolytes, d) on the valence of exchanging ions. The weighed-in portion of dried resin was shaken for 35-40 hours at room temperature with an exactly known volume of an electrolyte solution of a known concentration, and the concentration of the components in the solution was then determined. A resin with equal cross linking (7%), but different capacity (0.18 mg-equiv/l and 4.65 mg-equiv/l) was taken for the HY^+ - Ca^{2+} system. The coefficient of selectivity was calculated by B. P. Nikol'skiy's equation:

$$K = (x_{Ca}^{1/2}/x_{Ca})(m_H/m_H).$$

K, n are the equivalent portions of cations in resin and in solution, respectively. The following results were obtained for resin with the capacity 0.18 mg-equiv/l: for 0.895 N $CaCl_2$ $K = 0.35\pm0.13$ for 1.90 N $CaCl_2$ $K = 0.12\pm0.03$. For resin with a capacity 4.65 mg-equiv/l, K amounted to 8.99±0.82 for the first mentioned concentration of $CaCl_2$, and 4.75±0.07 for the second concentration. Resin, cross-linked with 7% and resin with 20% divinyl benzene displayed no change of selectivity in the HY^+ - Na^+ system. Resin with 7% cross linking displayed

Card 2/3

on a rising concentration of the external solution a reduced selectivity in the HY^+ - Na^+ and HY^+ - La^{3+} systems. With constant specific loading, the capacity, and cross linking, selectivity increased with the valence of the ion charge. There are 1 figure, 2 tables, and 11 references: 3 Soviet-bloc and 7 non-Soviet-bloc.

TITLE: Separation of lithium isotopes on cationites by means of sharp-edged moving bands

TEXT: The application of the method of F. Spedding, I. Powel, H. Swec (J. Amer. Chem. Soc., 77, 6125 (1955)) to separating the lithium isotopes on a КУ-2 (KU-2) cationite is described. Since neutralization of the H^+ form of the resin led to a temperature increase and to irreversible adsorption of lithium an NH_4^+ buffer band was used. First, 0.2 N NH_4OH was passed through a column with KU-2 in H^+ form. A 23-cm long NH_4^+ band was observed owing to the change in color of the resin. 0.2 N LiOH formed a 33-cm long visible Li^+ band. The bands were eluated by means of 0.25 N NaOH. The transition of the cationite from the Li^+ to the Na^+ form is not visible (no change in color). For calculating the separation factor α the authors

Card 1/2

Separation of lithium isotopes...

write: $N_{sol}(\alpha - 1)y = \sum_{i<i_n} v_i(N_i - N_o)$. N_{sol} is the molar fraction of Li^6

in the solution, y is the distance covered by the Li band, v_i is the length of the section from which the i-th sample had been taken, i_n is the coordinate of that point at which the isotopic composition is constant. For LiOH the following values were obtained in two types of KU-2: $\alpha = 1.0010 \pm 0.0003$ and $\omega = 1.0055 \pm 0.0003$. For Li_2SO_3, $\alpha = 1.0020 \pm 0.0005$. For a lithium band length of 33 cm, the separation factor was 1.32. There are 3 figures and 2 tables.

TITLE: Cross sections for dissociation of D_3^+ ions on D_2^+ and D^+ ions in collisions with deuterium molecules

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43, no. 3(9), 1962, 763-764

TEXT: The D_3^+ dissociation cross section resulting from single collisions with D_2^0 molecules were determined at energies between .30 and 100 kev of the D_3^+ ions, using a mass spectrometer with two magnetic analyzers. These collisions took place at $p \sim 3 \cdot 10^{-4}$ mm Hg in a collision chamber between two magnetic analyzers. The D^+ and D_2^+ formation cross sections $\sigma = I^* kT/Ipl$ have the following values

Card 1/2

Cross sections for dissociation ...

S/056/62/043/003/004/063
B125/B102

at the energies of the D_3^+ ions in kev		30	40	50	60	70	80	90	100
$\sigma(D^+)$		0.6	0.9	0.9	0.8	1.2	1.2	1.2	1.3
$\sigma(D_2^+)$		0.8	1.1	1.0	0.9	1.1	1.2	1.2	1.2

I^* and I are the secondary and primary ion currents, l is the effective length of the chamber. The increase of the cross section below 50-60 kev is probably due to the excitation of D_3^+ ions. The second increase of the cross sections at energies between 50 and 60 kev and more is due to the ionization of D_3^+ ions. The detachment of two electrons from the D_3^+ ions might be important at energies above 100 kev. The D^+ and D_2^+ production cross sections agree within the limits of measurement accuracy ($\sim 25\%$). There is 1 table.

AUTHOR: Tunitskiy, N.N.; Bagdasar'yan, Kh.S.   53

TITLE: Concerning resonance excitation energy transfer between molecules taking diffusion into account

SOURCE: Optika i spektroskopiya, v.15, no.1, 1963, 100-106

TOPIC TAGS: luminescence, energy transfer, diffusion, deactivation

ABSTRACT: The authors consider the time variation of the concentration of excited molecules in a luminescent solution under the influence of spontaneous deactivation and resonance energy transfer, the probability of which equals α/r^m, where r is the distance from the excited molecule to the quenching center and α is a constant. The problem reduces to solution of a diffusion equation with a sink. From the solution one can find the ratio of the steady-state rate of change of the concentration of excited molecules to the initial rate for $m = 4$ and $m = 6$. This ratio depends on the dimensionless parameter α/DR_0^{m-2}, where D is the diffusion coefficient and R_0 is the sum of the radii of the excited molecule and the quenching center. From comparison with the equations of coagulation theory there can be found the radius of the equivalent absorbing sphere. The authors also consider

Card 1/2

L 13103-63

ACCESSION NR: AP3003417

O

the problem of the concentration of excited molecules in the presence of a constant source of such molecules (steady excitation) and elucidate the roles of two excitation energy loss mechanisms for different values of the parameter in the two extreme cases when $D \rightarrow 0$ and when $D \rightarrow \infty$. There is a significant difference between the end results for the two cases for different values of α in the reasonable range from 10^{-30} to 10^{-33} cm^6/sec. TITLE: Investigating the effect of Co^{60} gamma-radiation on strong-base anionites AB-17 and AM

SOURCE: Atomnaya energiya, v. 16, no. 3, 1964, 245-249

TOPIC TAGS: anionite, gamma radiation, Co^{60} radiation, radioactive isotope, radiolysis, vacuum exsiccator, magnesium, trimethyl amine, gaseous product, exchange group, inert state, calcium chloride, nitric acid, carbonate ion

ABSTRACT: Experiments have been made on the radiation stability of the polymerization type anionites AB-17, containing 6 and 16% divinyl benzene (also referred to as AB-17X6 and AB-17X16), and AM by irradiating them in water with Co^{60}. The maximum total irradiation dose amounted to 4.7×10^8 roentgens. Before irradiation the anionite samples were changed into a hydroxyl form by a caustic soda solution and then carefully washed with water. After irradia-

Card 1/2

ACCESSION NR: AP4020332

tion, the anionites grew dark and their weight and volume became smaller. The resulting solution containing the radiolytic decomposition products of the anionites is foamy, acquires a yellow tinge, and becomes turbid because of the presence of a fine anionite fraction in it. Synthetic ionites are organic polymeric substances and are therefore affected by irradiation in the same way as are polymers. It should be borne in mind that the chemical action of the radiation may largely depend on the nature of the substance, that is, on the newly formed radicals and the probability of their interaction with the new compounds. Generally, however, the radiation stability of organic compounds, including ionites, is limited to a dose of the order of 10^9 roentgens. When irradiated with a dose of 4.7 x 10^8 roentgens, the relative volume of the AB-17X16, AB-17X6, and AM anionites is reduced by 35, 45, and 43% respectively. APPROVED FOR RELEASE: 03/14/2001   CIA-RDP86-00513R001757510004-1

ABSTRACT: This is a treatise prompted by the fact that preparation of high quality ion exchange resins and their regeneration is only possible if data about them both in steady as well as kinetic states are known. Ion exchange in steady state is well known, but there is a scarcity of information on ion exchange kinetics. This article consists of the following sections: 1. The fundamentals of ion exchange kinetics theory in which the following aspects are mathematically analyzed: a), diffusion through the solution film adjacent to the ion exchange resin at constant concentration of the outside solution; b) diffusion through the film at variable concentration of the outside solution; c) diffusion in the ion exchange particle at constant concentration of the outside solution; d) diffusion taking place simultan-

Card 1/3

ACCESSION NR: AP4033680

eously-both in the solution film and in the ion exchange resin particle. 2. The experimental methods of investigation in which two methods are used: a thin stationary layer (with constant concentration of the outside solution); an exchange between the solution and the ion exchange resin in a limited volume of solvent (with variable concentration of the solution). 3. Autodiffusion in cation exchange resins. The autodiffusion coefficient depends on a number of factors, among others - on the cross linkage rate, as determined with a quantity of divinylbenzene, temperature and ion charge. 4. Diffusion of ion microcomponents. When ions in microconcentrations - diffuse in the ion exchange resin, the cationic form of the latter remains unchanged. 5. Kinetics of full exchange. Here the ionic form of the cation exchange resin changes and no forecasts about a constant diffusion coefficient can be made since the ions being exchanged may have quite different mobility. In addition, when the cation exchange resin changes its form, its degree of swelling also changes. 6. Peculiarities in exchange kinetics of large organic ions. It is found that the rate of exchange depends on a number of factors: degree of cross linkage in the cation exchange resin, temperature, ion concentration in the solution and the cationic form of the cation exchange resin. 7. Relationship between diffusion and electroconductivity. Coefficient of autodiffusion

Card 2/3

ACCESSION NR: AP4033680

of ions in the ion exchange resin is determined by electroconductivity measurements.

TITLE: On the measurement of the kinetic energy of fragmented ions by means of a mass spectrometer. 1. Analysis of the line shape

SOURCE: Zhurnal tekhnicheskoy fiziki, v.34, no.3, 1964, 536-545

TOPIC TAGS: mass spectrometry, ion energy distribution, molecular ion dissociation, mass spectrometer line shape, faltung equation, nitrogen ion, nitrogen molecule ion

ABSTRACT: This paper is concerned with the measurement by means of a mass spectrometer of the energy distribution of atomic ions formed by the dissociation of excited molecular ions. To accomplish such a measurement it is necessary numerically to solve the faltung equation relating the observed line shape, the true line shape and the instrumental broadening, and then to solve a second integral equation relating the true line shape to the energy distribution in the center of mass system of the dissociating ion. These two mathematical processes are discussed in some detail. Concerning the solution of the faltung equation, the following two possibly useful suggestions are made: 1) It frequently occurs that the significant difference be-

Card 1/3

ACCESSION NR: AP4020586

tween the observed and the instrumental line shapes consists of relatively small
deviations in one wing, the effect of which may be masked in the numerical work by
random errors from the more intense central portion of the line. It is suggested
that in such a case the three functions involved be replaced by their products with
an appropriately chosen exponential function. The relation between the functions
remains that of faltung, and the effect of the wing shape in the numerical proce-
dure can be enhanced by properly choosing the exponential. 2) It is suggested that
the sharp central peak in the true line shape (when there is such) be represented by
a delta function. Means for determining the coefficient of the delta function are
discussed. The integral equation relating the true line shape to the ion energy dis-
tribution is derived on the assumption that the energy distribution is isotropic,
and approximate methods for solving it are discussed. The fraction of the total num-
ber of ions formed that enter the spectrometer (required for cross section measure-
ments), and the average energy, can be obtained from the first two moments of the
observed and the instrumental line shapes, without solving the faltung equation.
The cross sections for production of N^+ and N_2^+ by 140 eV electron impact, and the
energy distribution of the N^+ ions so produced, were determined by the methods dis-
cussed. A type MV-2302 mass spectrometer was employed, with a secondary emission

Card 2/3

ACCESSION NR: AP4020586

multiplier to record the ion current. The mean energy of the N^+ ions was about 3.3 eV, varying somewhat with the strength of the extracting field. The cross sections for producing N^+ and N_2^+ were equal within the 20% experimental error. This last result is not in agreement with the findings of other workers; the yield of N^+ has usually been found to be an order of magnitude less than that of N_2^+. Orig.art. has: 22 formulas, 2 figures and 1 table.

TITLE: Mass spectra of organic ions formed on a heated oxidized molybdenum surface in the residual gas atmoshpere within a mass spectrometer

SOURCE: Zhurnal tekhnicheskoy fiziki, v.34, no.8, 1964, 1441-1443

TOPIC TAGS: ion source, ionization, catalytic activity, mass spectrum, molybdenum compound

ABSTRACT: The mass spectrum was recorded of the heavy ions formed on the heated surface of a 10 x 10 x 0.05 mm^3 99.9% pure molybdenum strip which had been oxidized by heating in air for 20 hours at 450 to 500°C, and which occupied the source position in a type MI-1305 mass spectrometer. The temperature of the molybdenum strip was monitored with a thermocouple; the spectrometer was exhausted to 7 x 10^{-6} mm Hg with a mercury diffusion pump; and ions originating elsewhere than on the molybdenum strip were prevented from reaching the spectrometer proper by platinum shields. When the Mo strip temperature was 400°C, ion currents of the order of 10^{-12} A/cm^2 were observed at mass numbers 58, 72, 84 and 86; currents of the order of 10^{-3} A/cm^2

1/3

ACCESSION NR: AP4042932

were observed at mass numbers 99, 95, 101, 110 and 114; and smaller ion currents
were observed at mass numbers 59, 96, 111 and 112. All these ion currents behaved in
the same way when the Mo strip temperature was varied. The maximum current occurred
at 400°C. At lower temperatures the ion currents were smaller but stable, but at
higher temperatures the currents decreased exponentially with time. At 415°C the
time constants for the decrease of the most intense of the ion currents were in the
vicinity of 2 hours. When the strip was heated to 500°C the currents ceased within
a second and could be restored only by reheating the Mo strip in air. The results
are compared with those obtained by E.Ya.Zandberg and N.I.Ionov (DAN SSSR 141, 139,
1961) with oxidized tungsten, and obvious explanations are suggested for such dif-
ferences as exist. From the findings of J.W.Hickman and E.A.Gulbransen (Metals Tech.
AIME,T.P.2144,April,1947) concerning the formation of oxides on molybdenum surfaces
and the behavior of the ion currents with varying emitter temperature, it is con-
cluded that the active catalyst is MoO_3 and that the heavy ions probably contain
oxygen. It is suggested that the ions of mass number 58 and 72 may be $C_3H_6O^+$ and
$C_4H_8O^+$. Air containing 1% ethanol, propanol or toluol was admitted to the source
chamber at a pressure of 10^{-3} mm Hg. No increase in any of the ion currents was
thereby produced. Orig.art.has: 1 figure.

TITLE: The formation of the N sub 3 sup + and N sub 4 sup + ions in the mass-spectrometer

SOURCE: Zhurnal fizicheskoy khimii, v. 38, no. 4, 1964, 955-956

TOPIC TAGS: nitrogen, mass spectra, mass spectrometry, N sub 3 sup + ion, N sub 4 sup + ion, ionic current intensity, electron energy, formation cross section, sup 14 N sup 15 N sup ++ molecular ion, vibrational excitation, N sub 2 sup + ion, N sub 2 sup + ion

ABSTRACT: The mass spectra of nitrogen at pressures to 1×10^{-7} mm Hg was studied. The relationship between the ionic current intensities and the electron energies at m/e = 42 and 56 showed the mean potentials at which these peaks occur are 20.4 ± 1.3 and 46.5 ± 1 ev, respectively. The peak at 42 was considered to be the N_3^+ ion, the cross section of its formation is about 5×10^{-18} cm^2. The potential of the peak at 56 and of the double charged molecular ion $^{14}N^{15}N^{++}$ are close. Since there is no isotopic peak m/e = 57 it was concluded that N_4^+ is not formed, but that

Card 1/2

ACCESSION NR: AP4034581

the overcharged ion N_2^{++} is between the electric and magnetic fields of the mass spectrometer: $N_2^{++} + N_2 \longrightarrow N_2^{+} \quad N_2^{+}$. The cross section of this process is 1×10^{-15} cm^2 and is independent of the electron energy from 50-100 ev. To study the excitation of the initial ions, the relative intensity - electron energy relationship at m/e $\cdot$ 7 was examined. This peak results from the decomposition of the N_2^{+} ion ($N_2^{+} \longrightarrow N^{+} + N$) resulting from collision with nitrogen molecules in the area between the electric and magnetic fields. The increase in relative intensity with increased electron energy up to 35 ev (above this value the relative intensity decreases) is interpreted as vibrational excitation of the primary ion N_2^{+}. Orig. art. has: 3 equations and 2 figures.

sion, electron atom collision, mercury, xenon, krypton, argon, neon,
singly charged ion, doubly charged ion, electron impact ionization,
secondary ionization cross section, mass spectrometer background
ionization, metastable excited ion

ABSTRACT: This is a continuation of earlier investigations (ZhETF
v. 45, 815, 1963) of the ionization of singly and doubly charged
ions by electron impact. The method of intersecting ion and electron
beam was used to measure the cross sections for single ionization of

Card   1/#2

ACCESSION NR: AP4025915

the ions Hg^+, Xe^+, Kr^+, Ar^+, Ne^+, Hg^{2+}, Xe^{2+}, Kr^{2+}, and Ar^{2+}. The parent ions were obtained by ionizing the neutral atoms with a primary electron beam. The variation of the secondary ionization cross sections with the primary beam electron energy is determined. The ionization of neutral atoms by electron impact is found to be accompanied by formation of metastable excited ions with single, double, or triple charge. It is also shown that when the accelerating voltage is 2800 V, the background present in a mass spectrometer is due mainly to various ionization processes in which the metastable excited ions take part. Orig. art. has: 4 figures and 2 tables.

TITLE: Average momentum and energy of excitation of argon ions

SOURCE: Zh. eksper. i teor. fiz., v. 47, no. 2, 1964, 452-454

TOPIC TAGS: excitation, molecular physics, momentum transfer, ionization, mass spectrometry, argon

ABSTRACT: A method is described for determining the excitation energy of molecular ions, based on the measurement of the momentum transferred by the electron to the atom or to the molecule. This energy is in turn determined from the measured velocity acquired by the atomic or molecular ion. The positive ion velocity was measured with a mass spectrometer using the deflection method described by C. Berry (Phys. Rev. v. 78, 597, 1950). The experimental values of the momenta of several ions are presented, together with the cor-

Card 1/3

ACCESSION NR: AP4043615

responding excitation energies. For Ar^+ ions, the average energy transferred to the momentum by the ionizing electron turn out to be unexpectedly large, close to 50 eV. "The authors thank L. A. Vaynshteyn and I. I. Sobel'man for a detailed discussion of the results, and also V. G. Vasil'yev and S. Ye. Kupriyanov for many useful remarks." Orig. art. has: 2 formulas and 1 table.

TOPIC TAGS: mass spectrum, ion, kinetic energy, ion energy, electron energy

ABSTRACT: The problem of deviation of the actual mass spectra of ions from the corresponding true mass spectra is discussed. The larger the initial kinetic energy of an ion the greater its discrimination in the mass spectrometer. The relation between the ion energy distribution, determined from analysis of the line structure $\psi(E)$ and the initial ion energy distribution $\phi(E)$ is

$$\psi(E) = \frac{\text{const}}{V_1 V_3} E \, \phi(E),$$

Card 1/3

L 15194-66
ACC NR: AT5023428

where V_1 and V_2 are the two dimensions characterizing the orifice of the mass spectrometer. The collection coefficient P is equal to
$$P = \text{const} \frac{f_0 k_0}{f_0 k_1 - f_1 k_0},$$

where f_0 and k_0 are experimentally determined peak areas for ion and molecule, respectively and f_1 and k_1 are initial points of the respective mass peaks. It was found that there is a significant discrepancy between the literature data on mass spectra of ions of organic compounds (e. g. n-hexane) ionized with 70 ev electrons and their true values. A partial mass spectrum of n-hexane considering the initial energy of ions is shown in fig. 1. Orig. art. has: 1 figure, 2 formulas.

TOPIC TAGS: fluorescence, excited electron state, excited state, radiation effect

ABSTRACT: A mathematical treatment of the resonance mechanism of electronic excita-
tion energy transfer is given. This mechanism operates during extinguishing of fluo-
rescence of excited molecules B* by the acceptor molecules A, during sensibilized
fluorescence of A molecules, during inhibition of chemical decomposition of B* by A,
and during sensibilized photolysis or radiolysis of A molecules. For strong reso-
nance type excitation energy transfer, the radius of the molecular interaction R de-
pends only upon α and D where α is the energy transfer constant depending upon mole-
cule orientation and D is diffusion constant. R is independent of molecular dimen-
sion. In general the magnitude of α is within 10^{-33}–10^{-31} cm^6/sec range and the mag-
nitude of D is about 10^{-5} cm^2/sec; consequently, the magnitude of R is of the order

Card 1/2

L 10842-66

of 10^{-7} sec. The values of the effective molecular interaction radius R can be applied to the steady state process. If excitation energy transfer from B* to A results in chemical transformation of A and concentration of A is sufficiently small, then the steady-state concentration of A molecules is expressed by $\frac{dv}{dt} = -Nv.$

Ed.: B. S. Ram; Tech. Ed.: E.; P. V. Poguskin; Editorial Board: A. P. Vinogradov,
S. I. Val'fovich, N. M. Zhavronkov, M. I. Ivanov, Yu. S. Kletko, I. A.
Daneshariov (Scientific Secretary), S. S. Medvedev, B. D. Mel'nik, A. S.
Fisarzhsky, A. Du. Pryanuko (Chief Ed.), and A. V. Topchiev.

PURPOSE: This book is intended for the personnel of the chemical industry. It
will be of interest to the general reader interested in the development and
structure of the Soviet chemical industry.

COVERAGE: This book contains 19 articles on various aspects of the Soviet
chemical industry. Among the developments in the production of raw materials
for the manufacture of chemical products discussed are: 1) the use of raw
materials synthesized from natural gas and petroleum to replace food products
in the production of synthetic rubber, alcohol, detergents, etc.; 2) the synthesis
of acetylene from natural and petroleum gases for the production
of vinyl chloride, acrilonitrile, chloroprene, trichloroprene, 1-butadiene,
and other organic substances, based on methods developed by M. G. Kucherov,
A.E. Favorsky and others; 3) the production of acetylene from saturated
hydrocarbons by cracking (and its homologues) at 1350° in an electric
oxidation of ethane in a gas reactor, by pyrolysis (thermal
oxidation) of ethane in an improved furnace designed by B. S. Gribenko, by
high-temperature pyrolysis of propane and butane in tubular furnaces, or by
other methods of producing acetylene for the production of synthetic rubber,
ethyl alcohol, and other organic substances; 4) the synthesis of halogen deriv-
atives of aliphatic hydrocarbons for the production of solvents, refrig-
erants, pharmaceutical products, etc.; and 5) the production of rubber sec-
ondaries from nitrogen-containing aliphatic hydrocarbons. The history of
plastics production in the Soviet Union is reviewed, and trends, locations,
and products of plants as well as the names of outstanding personalities in
the field are given. The technical level and prospects of further develop-
ment of different branches of the plastics industries are also discussed

along with methods of manufacturing plastic articles. A special ap-
paratus designed by Ya. M. Mogilevskiy and designated "V" which permits
preparation of viscose solution in one operation is discussed. It is being
used to replace the complex, conventional equipment with great savings in
space. General trend is the technology of synthetic fiber production are
also discussed. A historical review of synthetic rubber production and
the achievement of outstanding Soviet scientists in this field are given as
will as names, locations and products of synthetic rubber plants. Rubber
production and the manufacture of rubber goods are similarly reviewed.
Statistical data and outstanding personalities in the development of the
acetylene dyes, paints and lacquers, mineral fertilizers, insecticides and
fungicides, sulfuric acid, soda, mineral salts, radioactive and stable
isotopes, and chemical reagents industries are given. Catalytic processes
and automation and automatic devices used in the chemical industry are
also discussed. Thirty-eight photographs included in the book show outside
and interior views of some Soviet chemical industry plants, as well as
their manufacturing, material-handling and laboratory equipment. Numerous
personalities and facilities are identified in the body of the text.
References accompany individual articles.

Properties of CaS-Bi and Mn-Phosphors.

Orig Pub : Tr. Fiz. in-ta AN SSSR, 1956, 7, 107-158

Abstract : The activator Bi in the CaS-Bi phosphor produces only one
radiation line of light at 20°C. At 77.3°, this line de-
composes into 2 systems of narrow equidistant lines depen-
ding on the influence of the lattice vibrations on the
electron transitions. In the CaS-Mn phosphor, the lumine-
scence of Mn is excited only in case of absorption in the
basic lattice and the lines 312 and 366 mμ are not effec-
tive. In the CaS-(Bi, Mn) phosphor, Bi serves as a sensi-
bilator, and these lines produce an intensive luminescen-
ce in the Mn band. The energy transfer takes place also

at low temperatures (-166°C). The absolute amount of the
transferred energy rises with the temperature rise, with
the rise of the excitation intensity and in case of irra-
diation with infrared light. The Bi line is extinguishing
according a linear law with the rise of the Mn concentra-
tion. If small amounts of Mn were introduced, the total
amount of light and the infrared flash increase considera-
bly. At this occasion, the basic activator (Mn) influen-
ces the flash spectrum, and Bi influences the spectrum of
the thermal de-excitation A scheme of energy transfer
by "induction resonance" analogous to the transfer in so-
lutions is offered. It is concluded that the interaction
of Bi and Mn in the CaS lattice results in a change in a
greater part of the phosphor properties with the excep-
tion of the radiation and absorption spectra.

TITLE: Luminescence mechanism and the band system of ZnS:Fe luminophors /Report,
Fourteenth Conference on Luminescence held in Riga, 16-23 September 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 4, 1966, 573-580

TOPIC TAGS: crystal phosphor, luminescence, zinc sulfide, thermoluminescence,
IR sensor

ABSTRACT: Although iron-activated zinc sulfide phosphors have been known since 1945,
the nature of their luminescence mechanism is still obscure. The writers developed a
synthesis procedure for ZnS:Fe phosphors in both powdered and sublimate form. The
initial ZnS, containing less than 10^{-7} g/g iron, was mixed with the desired amount of
Fe (none to 3×10^{-4} g/g) and heated at $1200°$ C for 90 min in a stream of HCl. Both
the powdered and sublimated specimens proved to be sensitive to infrared. ZnS without
Fe has one luminescence band peaking at 450 mμ; doping with Fe gives rise to another
band peaking at 630 mμ; the intensity of this red band increases with the dopant con-
centration, while the blue band gradually weakens. Figures in the text show the lumin-

escence spectra at different Fe concentrations and the dependences of the intensities
of the blue and red bands on the Fe content. Glow curves for the blue and red regions
are also shown. Evaluations are made of the trap depth. The glow curve data are con-
sistent with the results obtained in observing IR-stimulated flashes. A band scheme
with two levels near the bottom of the conduction band and two levels or groups of
levels near the valence band is proposed. Data on the infrared response are presented
and discussed. It is suggested that the trapping levels responsible for IR-stimulated
light flash may differ from the trapping levels responsible for the thermostimulated
peak at 155°, even though both sets of levels are located at about the same depth,
(0.06-0.07 eV). Aside from stimulation, infrared also proved to have a quenching
effect, particularly in a certain frequency range. The authors are grateful to Z. M.
Bruk, V. A. Minayeva and T. F. Filin for assistance in the work. Orig. art. has 9
